

REMARKS

Claims 1 to 21 are pending in the application, with Claims 22 to 29 having

been canceled, and with Claims 1 to 5, 8 and 10 to 12 having been amended herein.

*Claim
11
not amended.*
Claims 1, 11 and 12 are the independent claims. Reconsideration and further examination are respectfully requested.

Claims 1, 3, 5 to 7, 13 to 22, 24 and 26 to 29 were rejected under 35 U.S.C. § 103(a) over U.S. Patent No. 6,543,052 (Ogasawara) in view of U.S. Patent No. 5,530,758 (Marino, Jr.); and Claims 2, 4, 8 to 12, 23 and 25 were rejected under § 103(a) over Ogasawara in view of Marino, Jr., and further in view of U.S. Patent No. 6,385,655 (Smith). Reconsideration and withdrawal of these rejections are respectfully requested.

Turning to specific claim language, amended independent Claim 1 is directed to a method for the secure printing of print data from a client application residing on a data network to an interface device which has a printer, the interface device residing on a digital cable network which has a cable head end for interfacing the digital cable network to the data network. The method includes the steps of generating print data in the client application, determining whether secure communication paths exist between the client application and the cable head end, and between the cable head end and the interface device, transmitting, in response to a determination that the secure communication paths exist, the print data from the client application to the interface device, and sending the print data from the interface device to the printer for printing.

The cited art, namely Ogasawara and Marino, Jr., is not seen to disclose or suggest the foregoing features of amended independent Claim 1, particularly with respect to at least the features of generating print data in the client application, determining

whether secure communication paths exist between the client application and the cable head end, and between the cable head end and the interface device, and transmitting, in response to a determination that the secure communication paths exist, the print data from the client application to the interface device.

It is alleged in the Office Action that Ogasawara teaches the aforementioned mentioned features, except for the feature of determining whether a secure communication path exists between the client application and the interface device. Applicants again strongly disagree with this assertion. As mentioned in Applicants' previous Amendment, Ogasawara is seen to teach a method for providing internet access and internet shopping features in a digital cable environment, in which the user can purchase items over the internet using features such as voice and bar code recognition built into the remote control unit and the interface device. (Ogasawara, abstract; Figs. 3, 5A & 5B; and column 2, lines 13 to 44). With the invention described in Ogasawara, the user can purchase items over the internet using voice commands or by scanning a bar code of an item (Ogasawara, abstract; column 1; lines 61 to 65; column 3, lines 14 to 23; and column 5, lines 54 to 65). However, Ogasawara is not seen to disclose or suggest generating print data in a client application residing on a data network.

The client application of the present application is distinct from the specific purpose-type application software that includes voice recognition software and bar code recognition software as described in Ogasawara (Ogasawara, column 3, lines 14 to 23). In this regard, there is no mention of generating print data anywhere in the method described by Ogasawara. In the art described by Ogasawara, the purpose of the specific purpose-type application software is to allow an alternative means for the user to communicate to the

interface device to purchase merchandise over the internet, as opposed to only using a keyboard as an input method. The method of Ogasawara is not seen to disclose or suggest generating print data in a client application, where the client application resides on a data network separate from the cable head end, as in the present invention.

It is also alleged in the Office Action that the method of Ogasawara discloses generating and sending print data to a printer connected to an interface device. Applicants again strongly disagree with this assertion. Ogasawara is seen to disclose an interface device that has an external interface that can be connected to peripherals such as a printer, but there is not seen to be any mention in Ogasawara of where the print data is generated for printing on the printer. (Ogasawara, Fig. 1; and column 2, lines 41 to 44). The disclosure of having an external interface for connection to a printer is not seen in anyway to disclose or suggest the generation of print data in a client application which resides on a data network separate from the cable head end.

As stated in the Office Action, Ogasawara is not seen to disclose or suggest determining whether a secure communication path exists between the client application and the interface device. Therefore, Ogasawara cannot be seen to disclose or suggest determining whether secure communication paths exist between the client application and the cable head end, and between the cable head end and the interface device. Accordingly, it is not seen to be possible for Ogasawara to disclose or suggest transmitting, in response to a determination that the secure communication paths exist, the print data from the client application to the interface device and then sending the print data from the interface device to the printer for printing. Ogasawara is instead seen to disclose a method for the sending of voice data from the interface device to the remote control unit, wherein the voice data is

converted to analog voice data which is transmitted through a speaker on the remote control unit to the user. (Ogasawara, column 5, lines 53 to 65). The transmission of voice data is not seen in any way to disclose or suggest transmitting, in response to a determination that the secure communication paths exist, the print data from the client application to the interface device. There is not seen to be any mention in Ogasawara of checking for the presence of secure communication paths, much less determining whether to send print data from a client application to the interface device based on whether or not such the secure communication paths exist. Furthermore, the disclosure in Ogasawara of an interface device which is only seen to control a peripheral such as a printer and has an external interface with a peripheral is not seen to in any way disclose or suggest transmitting print data from the client application to the interface device, and sending the print data from the interface device to the printer for printing.

Marino, Jr. is not seen to remedy the foregoing deficiencies of Ogasawara, particularly with respect to the features of determining whether secure communication paths exist between the client application and the cable head end, and between the cable head end and the interface device. Marino, Jr. is seen to disclose a method of for secure communication between secure nodes in a computer network having unsecured nodes. (Marino, Jr., abstract; Figs. 1 & 2; and column 2, lines 7 to 24). In Marino, Jr., task 56 is seen to determine whether the destination entity is authorized to receive private data. (Marino, Jr., column 5, lines 42 to 44). According to Figure 5 in Marino, Jr., if the destination entity is authorized to receive private data, query task 60 determines whether secure link 30 is available for exchanging data with the destination entity. (Marino, Jr., Fig. 5). In determining whether secure link 30 is available, task 60 consults the IBAC table

48 in making its determination. (Marino, Jr., Fig. 4; and column 6, lines 62-66). However, the purpose of this determining step is either to secure an unsecured channel by passing the path name of the destination entity, and requesting a COMSEC secure channel initialization through security kernel 36, or to store information regarding the secure channel in channel ID table 68 by creating a channel ID and creating an association between the COMPUSEC attribute and the secure channel (Marino, Jr., column 6, lines 2 to 24 and lines 55 to 58). The step of determining whether secure link 30 is available in Marino, Jr. is not seen in any way to disclose or suggest the step of determining whether secure communication paths exist between the client application and the cable head end, and between the cable head end and the interface device, as in the present invention. In this regard, Marino, Jr. is not seen to be concerned with determining whether secure communication paths exist on each side of a cable head end which acts as an intermediary between a client application and an interface device.

The remaining art, namely Smith, is not seen to remedy the foregoing deficiencies of Ogasawara and Marino, Jr. In particular, Smith is seen to be directed to a method for securely delivering documents over an electronic network that uses special client applications on both the sender and recipient computers. (Smith, abstract; Figure 1; column 2, lines 58 to 67; and column 3, lines 1 to 15). Although Smith is seen to use a low-level secure communications protocol between the desktop computer and the dedicated server, nowhere is Smith seen to make a determination that secure communication paths exist between both the client application and the cable head end, and between the cable head end and the interface device, as in the present invention.

Based on the foregoing, Applicants respectfully submit that Ogasawara, Marino, Jr. and Smith, either alone or in combination, for which combination no motivation or suggestion is seen to be present, are not seen to render obvious the invention of amended independent Claim 1 because those references are not seen to teach the combination of features of amended independent Claim 1. Amended independent Claim 1 is therefore believed to be in condition for allowance, and such action is respectfully requested.

With respect to specific claim language, amended independent Claim 11 is directed to a method for the secure printing of print data from a client application residing on a data network to an interface device which has a printer, the interface device residing on a digital cable network which has a cable head end for interfacing the digital cable network to the data network. The method includes the steps of generating print data in the client application, determining that a secure communication path exists between the client application and the cable head end upon receipt through a secure protocol of a confirmation from the cable head end that the cable head end is a secure location, sending, in response to a determination that the secure communication path exists, the print data from the client application to the cable head end in a device-independent format, transforming in the cable head end, the print data from the device-independent format to a rasterized format which corresponds to the printer, determining that a secure communication path exists between the cable head end and the interface device upon receipt, through a secure protocol, of a confirmation from the interface device that the interface device is a secure location, and sending, in response to a determination that the secure communication path exists, the print

data in the rasterized format from the cable head end to the interface device for printing on the printer.

In this regard, amended independent Claim 11 is seen to include at least the features of amended independent Claim 1, in addition to other features. The applied art, namely Ogasawara, Marino and Smith, is not seen to teach or disclose the foregoing features of amended independent Claim 11, particularly with respect to *determining that a secure communication path exists between the client application and the cable head end* upon receipt through a secure protocol of a confirmation from the cable head end that the cable head end is a secure location, sending, in response to a determination that the secure communication path exists, the print data from the client application to the cable head end in a device-independent format, and *determining that a secure communication path exists between the cable head and the interface device* upon receipt, through a secure protocol, of a confirmation from the interface device that the interface device is a secure location, and sending, in response to a determination that the secure communication path exists, the print data in the rasterized format from the cable head end to the interface device for printing on the printer.

As discussed above with respect to amended independent Claim 1, the applied art is not seen to disclose or suggest determining that secure communication paths exist between the client application and the cable head end, and between the cable head end and the interface device.

Accordingly, Applicants respectfully submit that Ogasawara, Marino, Jr. and Smith, either alone or in combination, are not seen to render obvious the invention of amended independent Claim 11 because those references are not seen to teach the

combination of features of amended independent Claim 11. Amended independent Claim 11 is therefore believed to be in condition for allowance, and such action is respectfully requested.

Amended independent Claim 12 is directed to a method for the secure printing of print data from a client application residing on a data network to an interface device which has a printer, the interface device residing on a digital cable network which has a cable head end for interfacing the digital cable network to the data network, where the method includes the steps of generating print data in the client application, transforming, in the client application, the print data from a device-independent format to a rasterized format which corresponds to the printer, encrypting, in the client application, the print data in the rasterized format, sending the encrypted print data in the rasterized format from the client application to the cable head end, sending the encrypted print data in the rasterized format from the cable head end to the interface device, and decrypting, in the interface device, the print data in the rasterized format for printing on the printer.

The applied art, Ogasawara, Marino and Smith, is not seen to teach or disclose the foregoing features of amended independent Claim 12, particularly with respect to the features of transforming, in the client application, the print data from a device-independent format to a rasterized format which corresponds to the printer, encrypting, in the client application, the print data in the rasterized format, sending the encrypted print data in the rasterized format from the client application to the cable head end, sending the encrypted print data in the rasterized format from the cable head end to the interface device, and decrypting, in the interface device, the print data in the rasterized format for printing on the printer.

As discussed above, Ogasawara is not seen to be concerned with determining or ensuring a secure communication transfer from a client application to an interface device, much less performing encryption and decryption of print data for such a transfer. In this regard, Marino, Jr. is seen to teach a method of an integrity process 76 which verifies the integrity of the software running on secure processor subsystem 34. (Marino, Jr., Figures 2 and 8). In Marino, Jr., when the application is loaded onto the subsystem, a checksum may be generated and compared against a given value to insure the integrity of the application, wherein the checksum is generated, encrypted, and decrypted by task 82. (Marino, Jr., column 7, lines 15 to 22). This method taught by Marina Jr. is not seen to disclose or suggest generating print data in the client application, transforming, in the client application, the print data from a device-independent format to a rasterized format which corresponds to the printer, encrypting, in the client application, the print data in the rasterized format, sending the encrypted print data in the rasterized format from the client application to the cable head end, sending the encrypted print data in the rasterized format from the cable head end to the interface device and decrypting, in the interface device, the print data in the rasterized format for printing on the printer.

In this regard, Marino, Jr. is not seen anywhere to generate, encrypt and decrypt rasterized print data. Rather, Marino, Jr. discloses a method of generating, encrypting, and decrypting a checksum of the application that is loaded on the subsystem. Also, Marino, Jr. is not seen to disclose or suggest a source-to-end encryption of rasterized print data. The rasterized print data according to amended independent Claim 12 is encrypted in the client application. The encrypted rasterized print data remains encrypted in the cable head end and it is then decrypted in the interface device for printing by the

printer attached to the interface device. Again, this differs from the method of Marino, Jr. which is only seen to encrypt and decrypt the checksum of the application on the subsystem.

Smith is only seen to disclose the possibility of using various security methods, such as certificate authentication, for restricting access to the system to only authorized users. (Smith, column 20, lines 41 to 49). Nowhere is Smith seen to disclose or suggest the combination of rasterization, encryption and decryption between a client application, cable head end and a set-top box as in amended independent Claim 12. IN this regard, Smith defines the term "document" as any contiguous collection of data including platform-independent formatted document such as an HTML, PDF, or Envoy document. (Smith, column 4, lines 65 to 67; and column 5, lines 1 to 11). However, Smith is not seen to disclose or suggest transforming, in the client application, the print data from a device-independent format to a rasterized format which corresponds to the printer, encrypting, in the client application, the print data in the rasterized format, sending the encrypted print data in the rasterized format from the client application to the cable head end, sending the encrypted print data in the rasterized format from the cable head end to the interface device, and decrypting, in the interface device, the print data in the rasterized format for printing on the printer.

Based on the arguments set forth above, Applicants respectfully submit that Marino, Jr., Smith and Ogasawara, either alone or in combination, for which combination no motivation or suggestion is seen to be provided, are not seen to render obvious the invention of amended independent Claim 12 because those references are not seen to teach the foregoing combination of features of amended independent Claim 12. Amended

independent Claim 12 is therefore believed to be in condition for allowance, and such action is respectfully requested.

The other pending claims in this application are each dependent from the independent claims discussed above and are therefore believed patentable for the same reasons. Because each dependent claim is also deemed to define an additional aspect of the invention, however, the individual consideration of each on its own merits is respectfully requested.

Based on the foregoing amendments and remarks, the entire application is believed to be in condition for allowance and such action is respectfully requested .

Applicants' undersigned attorney may be reached in our Costa Mesa, CA office at (714) 540-8700. All correspondence should continue to be directed to our below-listed address.

Respectfully submitted,
